

Abstract

In the case of information offered from the Internet such as, for example, moving images, large quantities of data have to be transmitted, requiring a 5 large amount of bandwidth. This problem is solved, in that, in the transmission of large quantities of data, the Internet is excluded as a transmission path and the information is transmitted directly via the ISDN from the provider to the user, via a viewpoint, and the transmission quality is thus improved through combining what are to some extent inherently competing services, such as ISDN 10 and Internet.
